

Connecting copper plaques to cable trays in telecommunications equipment rooms

Overview

Some applications may require the cable tray to support the weight of a single, dead object in addition to the cable loads.

Key Takeaways

Copper grounding plaques should be securely bonded to cable trays using approved clamps, jumpers, or lugs to ensure electrical continuity and compliance with telecommunications grounding standards. Purpose of Grounding and Bonding

In telecommunications equipment rooms, grounding and bonding are critical to protect equipment and personnel from electrical faults and to maintain signal integrity. Cable trays often carry metallic cables and can serve as part of the equipment grounding system, but they must be electrically continuous and properly bonded to the telecommunications grounding infrastructure .

Methods for Connecting Copper Plaques

- Direct Bonding with Clamps or Lugs Copper plaques can be attached to the side of a cable tray using bolts with tin- or zinc-plated lugs. Drill the tray side and secure the plaque with a 1/4-inch fine-thread bolt or equivalent hardware, ensuring a tight mechanical and electrical connection .

- **Use of Bonding Jumpers** Where cable tray sections are not electrically continuous, manufactured copper bonding jumpers or braided copper straps can bridge gaps. These jumpers should be sized according to the equipment grounding conductor requirements and connected to both the tray and the copper plaque .
- **Split Bolts or Auxiliary Brackets** In some installations, split bolts on cable baskets or auxiliary cable brackets on ladder racks are used to secure copper plaques. These methods provide both mechanical stability and reliable electrical continuity .
- **Insulated Conductors for Aluminum Trays** If the cable tray is aluminum, avoid bare copper to prevent electrolytic corrosion. Use an insulated copper conductor, removing insulation only at bonding points to the tray or plaque .

Best Practices

- Bond both side rails of ladder or trough cable trays to ensure full electrical continuity .
- Verify connections visually and electrically; measure resistance to confirm low-impedance paths to the telecommunications grounding bus .
- Follow industry standards such as IEEE Std. 1100, TIA-942, J-STD-607-A, and BICSI TDMM for telecommunications grounding .
- Avoid using cable trays as the sole grounding path for circuits with high ground-fault protection ratings; supplement with dedicated copper conductors if necessary .

Integration with Telecommunications Grounding System

Copper plaques should be connected to the Telecommunications Main Grounding Bus (TMGB) or Telecommunications Grounding Busbar (TGB). This ensures that all metallic components, including cable trays, racks, and enclosures, share a common reference potential, minimizing the risk of voltage differences and improving system reliability . By following these practices, copper plaques can be effectively integrated into cable tray systems, providing safe, reliable, and standards-compliant grounding in telecommunications equipment rooms.
