

Grounding Requirements for Industrial Distribution Boxes

Overview

NEC Article 250 defines the grounding and bonding requirements for every industrial electrical installation.

Key Takeaways

Industrial distribution boxes must be grounded using properly sized conductors, bonded to a central grounding system, and tested to ensure low resistance for safety and compliance. Regulatory and Safety Standards

Grounding in industrial facilities is governed primarily by NEC Article 250 in the United States, which establishes the framework for grounding electrode systems, equipment grounding conductors, and bonding of metallic components to protect personnel and equipment from electrical faults. OSHA standards also require proper grounding to prevent shock hazards and ensure operational safety. Grounding provides a low-impedance path for fault currents, allowing overcurrent protective devices to operate effectively and safely.

Equipment Grounding Conductors

- Wire sizing: For U.S. installations, a 10 AWG (5.26 mm²) ground wire is typically required for distribution boxes, while other international markets may use 6 mm².
- Connection points: Attach a ground wire from a threaded stud at the bottom of the distribution box to the mounting plate, then from the mounting plate to the facility's central grounding point.

- Resistance requirements: The total ground resistance between system components should be less than 0.1 Ohm to ensure proper fault clearing .

Grounding Multiple Spindles or Tool Connections

- Alternative 1: Use a 16 mm² ground wire (or 6 AWG in the U.S.) from the mounting plate to the spindle plate to maintain low resistance regardless of tool cable length or number of spindles .

- Alternative 2: For tool cables up to 30 meters, the extra ground wire may be omitted if multiple spindles are grounded together, as parallel connections reduce total resistance to a safe level .

High-Resistance and Solid Grounding Considerations

- High-resistance grounding (HRG): In some industrial applications, HRG is used to limit line-to-ground fault currents, reduce arc-flash hazards, and maintain service continuity during faults .
- Solid grounding: Provides a direct path to ground but can create higher fault currents and potential arc-flash hazards. HRG is often preferred in sensitive or critical systems.

Testing and Maintenance

- Resistance testing: Every installation should be tested to ensure maximum resistance does not exceed 25 Ohms for general safety, with stricter limits (e.g.,
