

Where is the power distribution box installed in a machine-room-less elevator

Webit Cabling

Overview

The location of power delivery varies with the manufacturer and elevator type and must be coordinated.

Key Takeaways

In machine-room-less (MRL) elevators, the power distribution box is typically installed inside the elevator shaft or in a cabinet at the top floor, accessible for maintenance and emergency operations.

Typical Placement
For MRL elevators, the power supply box contains all the main power components and is generally located within the elevator shaft itself, rather than in a separate machine room . This allows the system to remain compact and eliminates the need for a dedicated machine room. In some designs, a cabinet at floor level, usually on the top floor, houses the main electronic components that require interaction with technical staff, while the power box remains in the shaft .

Accessibility Considerations

The power box is designed to be accessible for maintenance and emergency operations, such as manual lowering of the elevator or accessing cut-off valves and controls . Access panels are typically provided to allow technicians to reach these components safely without removing the entire unit. The installation height is dictated by the need to reach emergency controls and valves easily.

Compliance with Electrical Codes

According to NEC requirements, in elevators without a machine room, the overcurrent device or disconnecting means must be located outside the hoistway and accessible only to qualified personnel . This ensures safety while maintaining compliance with electrical standards. The power distribution box may include fuses or circuit breakers designed to coordinate with the elevator controller for proper fault protection .

Summary

- Power components: Installed in a shaft-mounted power box.
- Control electronics: Often in a cabinet at the top floor or integrated into the shaft.
- Access: Panels provided for maintenance, emergency lowering, and valve control.
- Code compliance: Disconnects or overcurrent devices must be accessible to qualified personnel and meet NEC coordination requirements. This configuration allows MRL elevators to operate efficiently without a separate machine room while ensuring safety, accessibility, and compliance with electrical standards.
